EgoQuant: speaker notes for the 10-minute presentation

2026 Shenzhen FinTechathon · WeBank International Track · Topic B: Wealth Advisory Agent. About 45 seconds a slide; the notes are about 80 words each (140 words a minute). Say "hypothetical" and "simulated" whenever a chance or a loss is mentioned; never "we recommend" or "guaranteed".

Slide 1 (0:00) · EgoQuant: Your portfolio should understand you

Good afternoon. EgoQuant is a wealth-advisory agent built on one rule: every number that matters comes from deterministic, tested code, and the AI only explains. In ten minutes I will show the journey an investor takes, the safety design behind it, what we measured, and what we did not build. Everything I say names a file, a test or a measured number in our documents.

Slide 2 (0:45) · The problem a retail investor has

A retail investor cannot judge whether a portfolio is suitable, cannot see why it looks the way it does, and cannot prove later what they were told. EgoQuant answers each of these with a promise: Fit, the portfolio is suitable for this person; Proof, every number has a reason, a source and an independent check; Trace, what we advised can be shown unchanged later.

Slide 3 (1:30) · The one rule that organises the system

This is the rule behind everything you will see. Scores, categories, limits, weights, approvals and trade verdicts are code. The language model explains results it is given; it can run the real engine through two whitelisted tools, but it cannot invent a number, because every number it says is checked against the engine's facts. The one exception, the news-tone label, is labelled as such and never touches a number. And an independent Risk Engine re-checks the finished portfolio from scratch and fails closed.

Slide 4 (2:15) · The journey: about ten minutes, five steps

The journey takes about ten minutes. A validated questionnaire gives the risk category and its limits. A short Risk Game adds behaviour. The investor picks what they would like to hold, and only what their category allows can be ticked, with the reason shown for everything else. The portfolio is built on real prices and approved by the Risk Engine, with the chance of reaching the goal shown as N in 100 simulated futures. Finally the plan is reviewed, confirmed and sealed, and anyone can verify the sealed report later. LIVE DEMO (30 seconds, no sign-in): open fintechaton-frontend.vercel.app/verify, press Use the demo report (Unchanged, Sealed for demo_investor, block 11,951,549), then Try a tampered copy (Does not match). If asked for an operation log: the dated deploy-check file in the evidence folder (71 of 71 checks on the live service, 20 Oct) and the fourteen-investor run log (30 builds, 26 trade checks, 14 what-ifs, 0 rule failures).

Slide 5 (3:00) · Suitability by design: the lower of willing and able

Suitability asks for the more cautious of willing and able, so the category is the lower of the two. Attitude is measured with Grable and Lytton's published scale, quoted word for word, blended two thirds with one third from the Risk Game. Knowledge, from Lusardi and Mitchell's Big Three, gates complex products but never changes the category. Capacity averages four answers, with two hard caps: money that must come

back, and a short horizon. The numbers behind each category are our provisional placeholders, kept in one file so a bank can replace them, and every report says so.

Slide 6 (3:45) · Six specialised parts, one independent check

Why several agents rather than one prompt? Separation of duties. Each part does one job in deterministic, tested code: market data, portfolio construction, behaviour, and the final check. Agent C builds the allowed universe and prices it with real data. Agent A builds about a hundred candidates inside every hard limit and simulates the goal. Agent B reads real behaviour and can only tighten. The Risk Engine does not trust the optimiser: it re-computes everything and fails closed. The news briefing and the advisor sit beside the numbers and never change them.

Slide 7 (4:30) · Behaviour counts, and can only make it safer

What people say and what they do differ. The Risk Game gives everyone a behavioural signal, bounded to one third of the attitude and never past the capacity cap. A real trade history is stronger evidence and can only tighten. In the demo, an invented account that sold in two market falls moves the loss limit from twenty to under nine percent and the stock share from twenty-three to eight percent, and the Limits tab shows exactly where that line came from.

Slide 8 (5:15) · A goal simulation that is honest about history

To say how likely a goal is, we replay the past: ten thousand futures stitched from real months of market history, with a regime model deciding which kind of month comes next so that crises last as long as they did. Two corrections keep history's luck out: today's interest rates for bonds and cash, and a hindsight correction for stocks. We ran a calibration backtest on our own method. It beats the plain bootstrap over all dates, but the gain on later dates is within the noise, and realised outcomes can differ from the simulated chance by tens of points. That is why the product says simulated and never probable.

Slide 9 (6:00) · The advisor can run the engine but cannot decide

The advisor is fenced in. It can run the real engine through two whitelisted tools, but it has no write path to any score, limit or verdict. Every number it says must come from the engine's facts or the user's own words, or the reply is regenerated and then replaced by a safe fallback. Personal data is replaced by placeholders before any model call, and a compliance guard withholds anything that reads like a trade instruction or a forecast. We ran the live red-team on the final version today: 41 of 42 cases and 51 of 51 trade explanations pass. The first run found a real bug in the chat's trade tool, which we fixed within the hour and re-ran; the one remaining flag is a false alarm of our own check.

Slide 10 (6:45) · Security and compliance: what we built and what we measured

Security is thirty percent of the score, so here is what we measured. Three and a half thousand automatic tests, with hostile-input suites, property sweeps and mutation checks where we broke the code on purpose to see the tests fail. A read-only deploy check passes seventy-one of seventy-one on the live service. The dependency audit found nothing. And we list twenty-eight known gaps with owners, next to a threat table, because a limit that is written down can be defended. Users are isolated by Row-Level Security with no privileged key anywhere; data is minimal, expires, and can be erased completely.

Slide 11 (7:30) · Tamper-evident advice: the on-chain seal

Trust needs a trace. When a plan is confirmed, we fingerprint the exact report the person saw, together with a record of the advice, and publish only that fingerprint on a public test chain. Anyone can later check the downloaded report on the Verify page without an account: change one number and it fails. These are real transactions; the block numbers are on the slide and every seal is listed with its link. We are precise about what it proves, that this report existed unchanged for this person, and what it does not: that the advice was right. The same format would move to a consortium chain such as FISCO BCOS.

Slide 12 (8:15) · Honest limits, and what we would do next

We say what is not done. EgoQuant is a prototype, not a regulated service; its limits are placeholders. The Risk Game is not psychometrically validated, so it is bounded. The simulation is not a probability. The data is a snapshot accepted for the competition only. It is English only, one broker only, on a test network, and without an external penetration test. The roadmap follows directly: institutional calibration, validation of the game, licensed data, a consortium chain, Chinese-language advice and assurance.

Slide 13 (9:00) · Try it yourself

You can try everything yourself. Two minutes without an account on the Verify page, ten minutes with the demo account through the whole journey. Nine documents and the tagged code carry the evidence. Every limit in EgoQuant is a proposal, every simulation is hypothetical, and every claim names a file, a test or a measured number. Thank you.
